

Open Issues & Pending Work

Semivra Libellus POS — v1.1

Internal review document. This report lists what still needs to be done before the system reaches its full planned feature set. Written in plain language for business owners and decision makers.

Document Type

Open Issues & Pending Feature Report

System Version

v1.1 (May 30, 2026)

Overall Status

Operational — approximately 85% complete toward full feature set

s3mivra@gmail.com

About This Report

May 2026

This report is for the development team and any stakeholders who need to understand the current state of Semivra Libellus — specifically what is not yet done, what has known limitations, and what is planned for future versions.

Issues are grouped into four priority levels so you can judge what should be fixed before launch, what can be improved over time, and what is a nice-to-have for the future.

Issue Summary at a Glance

0

CRITICAL

No blocking issues. The system is operational.

3

HIGH

Should be fixed before full client launch.

6

MEDIUM

Important improvements for growth and reliability.

5

LOW / FUTURE

Nice-to-have features for future versions.

Important context: The system is fully operational today. Cashiers can take orders, inventory is tracked automatically, and accounting journals are generated on every transaction. The issues in this report are improvements and missing features — not reasons to stop using the system.

High Priority Issues

May 2026

These three issues pose the greatest operational risk and should be resolved before the system is launched to paying clients.

H-01 **HIGH** The admin panel is one very large file (4,825 lines)

What is it?

The complete POS interface — orders, inventory, accounting, analytics, and settings — is all written in a single code file that is now 4,825 lines long. Think of it like a physical notebook where every department's records are crammed together with no dividers or organisation.

Impact on you:

When a developer needs to fix or add something, they work inside this one giant file. A mistake in one section can accidentally break something in a completely different section. As the system grows, updates become slower and riskier. This directly increases the cost and time of future customisation.

How to fix it:

The file needs to be split into smaller, organised parts — one file per major section (Orders, Inventory, Accounting, Analytics, Settings). This is a code organisation task only and will not change anything visible to users. Estimated effort: 3–5 working days. Planned for version 1.2.

H-02 **HIGH** No offline mode — an internet outage stops operations

What is it?

If the internet connection goes down while the POS is being used, cashiers cannot submit new orders or save data. There is no "work offline and sync when back online" feature. It is similar to a cash register that stops working when the electricity flickers.

Impact on you:

During peak café hours, an internet outage — even for 10 to 15 minutes — means orders cannot be processed digitally. Staff must take orders on paper and enter them manually after reconnecting. This is a real risk given the inconsistency of some Philippine internet providers.

How to fix it:

The recommended mitigation today is to run the POS server on a local router inside the café (LAN setup), so the system works even if the internet goes down — only cloud backups need internet. A full offline mode with sync is a major engineering project (estimated 4–6 weeks) and is on the roadmap.

H-03

HIGH

Receipts do not print automatically — browser dialog required

What is it?

When an order is completed, the receipt appears on screen. To print it, the cashier must click a "Print" button which opens the browser's standard print dialog — the same one used for printing documents or web pages. Every single receipt requires this extra step.

Impact on you:

This slows down the checkout process compared to systems where receipts print instantly with no extra interaction. It also means there is no automatic kitchen ticket printing when an order is submitted — kitchen staff rely entirely on the screen.

How to fix it:

Integrating with a Bluetooth or USB thermal receipt printer (common 58mm or 80mm models sold in the Philippines for ±800– ±3,000) would solve this. A local print server can bridge the gap without changing the main application. Estimated development effort: 1–2 weeks.

Medium Priority Issues

May 2026

These issues do not block daily operations but are important improvements for long-term stability, growth, and a better staff experience.

M-01 **MEDIUM** **Analytics calculations run on the device and may slow down over time**

What is it?

All charts and sales summaries are calculated inside the browser using the full order history loaded from the server. For a new café with a few weeks of data this is fast. But after a year of operation with tens of thousands of orders, loading and processing all that data may cause sluggishness on older tablets.

Impact on you:

On an Amazon Fire tablet or older Android device, the analytics tab may take several seconds to load or may feel unresponsive as order volume grows. Staff experience degrades, not functionality.

How to fix it:

Move the heavy calculations to the server so the browser only receives pre-computed summary numbers. The browser then just displays the results — no heavy processing needed. Estimated effort: 3–5 days of backend work.

M-02 **MEDIUM** **Only one café branch per installation**

What is it?

Each installation of Semivra serves one physical location. If you open a second branch, you need a separate server, separate database, and a separate URL for that branch. There is no combined management view or consolidated reports across both.

Impact on you:

As the business grows beyond one location, managing two separate systems becomes inconvenient. You would need to log in to each separately and manually combine the numbers to see total business performance.

How to fix it:

Add a "branch" layer to the data model so one installation can manage multiple locations with a combined management view and per-branch reports. This is a significant architectural change — estimated 3–4 weeks of development. Planned as a future version.

M-03**MEDIUM****No sound or pop-up alert when a new QR order arrives****What is it?**

When a customer submits an order through the QR dine-in menu, there is no sound, vibration, or pop-up notification on the cashier's device. The order appears in the queue, but only if a staff member is actively looking at the screen.

Impact on you:

A busy cashier handling multiple tasks — taking payments, packing takeout orders, answering questions — might miss a new QR order for several minutes. This reduces the speed-of-service benefit that QR self-ordering is supposed to provide.

How to fix it:

Implement an audio chime or bell sound that plays automatically when a new order arrives. This is a small change — estimated 2–3 days. Web Push Notifications (alerts even when the browser tab is minimised) are a more complete solution requiring additional setup.

M-04**MEDIUM****All connected devices receive all real-time updates****What is it?**

When any order is updated — prepared, delivered, or cancelled — every device currently logged in receives that notification simultaneously. The cashier's tablet, the manager's laptop, and any kitchen screen all get the same event, even if it does not apply to them.

Impact on you:

With 2–3 devices this is not a problem. But as more stations are added — a dedicated kitchen screen, multiple cashier tablets, a manager's office device — the system sends unnecessary data to all of them. Not a current issue, but will become inefficient at scale.

How to fix it:

Implement channel-based routing (called "rooms" in the technology used) so kitchen devices only receive kitchen events and cashier devices only receive checkout events. Low risk, estimated 1–2 days. Scheduled for when the number of connected devices grows.

M-05**MEDIUM****Legacy admin accounts may be missing the correct role assignment****What is it?**

When role-based access was introduced, a startup script was written to automatically update any old "Super Admin" accounts that were missing the role field. This script runs automatically when the server starts. However, if the server starts in an unusual way that bypasses the normal startup sequence, those accounts could silently lose Super Admin access.

Impact on you:

Edge case scenario: an old admin account loses its role flag without any obvious error message. The manager tries to access financial reports or user management and receives an "access denied" message — confusing and alarming in the middle of operations.

How to fix it:

Run a one-time database migration to permanently fix all legacy accounts independently of server startup behaviour. Low effort — estimated half a day. Very low risk, but worth doing before the system is handed over to a client.

M-06**MEDIUM****No customer loyalty or rewards programme****What is it?**

There is no built-in customer points system, stamp card, or repeat-customer discount. Discounts can be applied manually by the cashier at any time, but the system does not automatically recognise returning customers or accumulate rewards across visits.

Impact on you:

Loyalty programmes are a common and proven retention tool for Philippine cafés. Without one, you cannot offer "buy 10 get 1 free" or points-based rewards without tracking it in a separate notebook or spreadsheet.

How to fix it:

Add a customer profile model with a phone number or name as the identifier, a points balance, and configurable rewards rules. The cashier could look up a customer at checkout and apply accumulated points. Estimated development effort: 1–2 weeks.

Low Priority / Future Features

May 2026

These items will not affect daily operations. They are improvements and additions planned for future versions of the system.

L-01 No native mobile app (iOS or Android)

What is it?

The system runs in a web browser. While it works reasonably well on a mobile browser, there is no dedicated app available on the App Store or Google Play Store that staff can install on their phones.

Impact:

Staff cannot receive push notifications on their personal phones. The browsing experience on small phone screens is functional but not optimised for phone-sized layouts.

How to fix it:

Build a Progressive Web App (PWA) version — this can be "installed" from the browser and behaves like a native app without requiring App Store submission or approval. Estimated: 2–4 weeks.

L-02 No payment terminal integration

What is it?

When a customer pays by GCash or Maya, the cashier manually selects the payment method after the customer shows their confirmation screen. There is no physical terminal that automatically verifies the payment.

Impact:

Slight risk of cashier selecting the wrong payment method by mistake. Slightly slower checkout compared to tap-to-pay terminals, which auto-confirm the payment.

How to fix it:

Integrate with the GCash for Business API or a third-party payment terminal SDK. This depends on obtaining a merchant agreement with the payment provider. Estimated development time: 2–3 weeks once API access is provided.

L-03 No dedicated kitchen display screen (KDS)

What is it?

Kitchen staff currently use the same order queue screen as the cashier, or a separate browser window showing the same interface. There is no screen designed specifically for kitchen use — large text, clear status buttons, audio alerts.

Impact:

Kitchen staff workflow is less efficient than a purpose-built kitchen display. Orders may be missed on busy days if no dedicated kitchen screen is set up.

How to fix it:

Build a read-only kitchen-facing view showing only pending and in-progress orders, with large touch-friendly buttons to mark each order as ready. Estimated: 3–5 days of frontend work.

What is it?

There is no supplier contact book or formal purchase order (PO) workflow in the system. When stock runs low, the operator contacts the supplier manually and then enters the restock into the system by hand.

Impact:

Restocking is a fully manual process. There is no automated "generate a purchase order when stock falls below the threshold" feature, and no way to track which supplier provides which ingredient.

How to fix it:

Add a supplier model (name, contact details, products supplied), a PO creation and approval workflow, and a "receive against PO" restock flow. Estimated: 1–2 weeks of development.

L-05 No customer-facing display (second screen)**What is it?**

A customer-facing screen — like the second monitor you see at a supermarket checkout showing your items and total — is not yet available. Customers cannot see their order building up as the cashier adds items.

Impact:

This is a transparency and trust improvement rather than a functional gap. Most small cafés do not need it, but larger operations with a counter setup may want it.

How to fix it:

Create a second browser window or TV-connected display mode that shows the current order in large, clear text. Estimated: 2–3 days of frontend work.

What Is Fully Working Today

May 2026

To provide complete context alongside the issues above, here is the full list of everything verified, tested, and working correctly in version 1.1.

- POS cashier interface: product search, add-ons, discounts, payment methods, change calculator
- Customer QR dine-in self-ordering: scan QR !' browse menu !' submit order !' appears in queue
- Six fulfillment modes: Dine-In, Takeout, Pickup, Manual Delivery, Grab Delivery, Foodpanda
- Delivery dispatch pipeline: Preparing !' Out for Delivery !' Delivered
- Delivery details capture: address, customer phone number, delivery fee, scheduled time
- Partial delivery state: "Give Partial — More Items Coming"
- Complimentary (free) orders with cost-only accounting
- Void completed orders with full accounting reversal (Super Admin only)
- Shift start with starting cash entry by the cashier
- End-of-shift reconciliation: expected vs. actual cash, variance logged
- Shift history archive with variance colour coding
- X-Reading mid-shift PDF generation
- Real double-entry journal ledger — automatic entry on every transaction
- Automatic COGS (cost of goods sold) calculation on every sale
- Accounts Receivable tracking for e-wallet and delivery platform payments
- A/R settlement workflow: mark as received and record deposit destination
- Profit & Loss Statement with custom date range
- Balance Sheet with accounting equation verification
- Expense entry with journal posting and category tracking
- Chart of Accounts with standard Philippine SME account codes (1000–6200)
- Inventory tracking: stock levels, restock, and full stock movement history
- FEFO batch consumption: oldest expiry date always consumed first
-

- Multi-batch inventory: separate tracking per delivery receipt
- Expiry date monitoring with colour-coded badges (expired, warning, safe)
- Low-stock alerts on sidebar and on each inventory row
- Spoilage / waste logging with automatic accounting journal entry
- Excel / CSV stock-take import with diff preview and confirmation step
- Display units: operators see kg / L / pcs everywhere — never raw grams or millilitres
- EOD physical count audit in display units (kg/L/pcs)
- Role-based access: Staff vs. Super Admin with locked sections
- Login rate limiting: brute-force protection on the login page
- Atomic inventory deduction: no double-counting during simultaneous orders
- Non-VAT compliant receipts with BIR-required "NON-VAT REGISTERED" label
- Docker deployment containers: one-command server setup
- GitHub Actions CI: automated build and test checks on every code change
- 75 automated tests: accounting logic, unit conversion, and batch math all verified
- Structured production logging for server monitoring and debugging
- Health check endpoint for uptime monitoring by load balancers

Overall assessment: Semivra Libellus v1.1 is a production-ready POS system. The 3 high-priority issues represent real operational risks that should be addressed before full commercial deployment. The medium and low items form a healthy development backlog — not blockers. A business using this system today has a more capable and more auditable back-office than the majority of Philippine SME cafés.
